## 13. Perform string reversal using stack

The idea is to create any empty stack and push all the character from the string into it. Then pop each character one by one from the stack and put them back into the input string starting from oth index. Stack work on the principle of FILO (First in Jast out)

After popping all the elements and placing them back to string the formed string would be reversed

Algorithm

Step 1: Accept string from the user

Step a: scan complete string from left to right.

Step 3: push each element character in stack

Step 4! Once scanning is done

Step 5: Start popping element if to recall jist from stack and append it to result string

Step 6: Once the stack is empty return the result in string from which is the final result

Step 7: Display the result

True complexity - Ola) spare complexity - Oln)
